## 1. Keyboard layout

The RPN-1250 keyboard has 24 keys.

The basic functions of each key are written in white below the key concerned. The functions writed in orange above each key, on the left, are activated by preceding

the press of the key concerned by a press of the F key.

The functions writed in blue above each key, on the right, are activated by preceding the press of the key concerned with two presses of the F key, i.e. the equivalent of G.

RPN-1250 Page 5 RPN-1250 Page 6

#### Overview

software is programmed in **C** with the Microchip **MPLAB X IDE**. Microchip PIC 18F2680 flash chip with an 8-digit, 7-segment MAX7219 LED driver. The Based on a Texas Instruments TI-1250 calculator, the RPN-1250 calculator has a 64 KB

The **RPN-1250** calculator has 98 program steps and 20 registers in volatile memory.

These programs and registers can be saved, in programming mode, in three different constant memory areas.

- 4-level scientific RPN stack with conversions,
- 20 memories (0 to 9 and .0 to .9) with arithmetic store and recall,
- Possible backup of the stack and registers in the "constant" flash memory of
- 98 programmable steps (like the HP-29C) with alphanumeric display of
- 3 program saving areas in the "constant" flash memory of the PIC
- 20 labels (0 to 9 and .0 to .9),
- subroutines (GSB, RTN),
- 12 possible tests (X=0, X<>0, X=y, X<>y, ...)
- PAUSE and VIEW functions,
- step by step execution (SST),
- conversions (in<>mm, mi<>km, lb<>kg, °F<>°C)
- Speed ??approximately 8 times higher than an HP-41C...

Deviations from the HP-29C calculator:

- No increment or decrement instructions (ISZ, DSZ)
- No indirect addressing
- No absolute value (ABS) [replaceable by x<0? CHS]
- No polar/rectangular conversions

## 4. How to use the calculator

The **RPN-1250** calculator is equipped with a single-line, 8-character (alpha)numeric

Power is provided by a 9 Volt 6LR61 battery and the calculator turns on and off using the switch located on its left :

- ON: positioned at the top,
- OFF: positioned at the bottom.

## 3 modes of use are possible:

### "Execution" mode

is the mode in which the calculator is used to make calculations and conversions or launch the execution of the program loaded in volatile memory

calculator is turned on, but can be kept in constant memory. The stack and the used registers, being in volatile memory, are reset each time the

allows saving of the stack and registers in constant memory.

 $\mid$  LD  $\mid$  allows you to reload the stack and registers from constant memory.

The execution of a program loaded in volatile memory is done

execution (after entering the data required by the program) - either by positioning at the start of memory (step 00) via RTN then :o launch

data required by the program) concerned (0 to 9 or .0 to .9) then  $\left| \mathbb{R} \right|$  to launch the execution (after entering the - either by positioning at the starting label of the program via 🗺 following the labe

à 9 ou .0 à .9) (after entering the data required by the program) - either by directly launching the program via GSB followed by the label concerned (0

and using SST to advance step by step A program can also be executed step by step to check that it is functioning correctly. The launch is done in this case by positioning in the program either by RTN or by STO

### "Program" mode

is the mode in which programs are entered and can be edited

### "Esc." mode

 $\Rightarrow$  is the mode in which the brightness can be adjusted.

⇒ a display test can also be performed.

 $\Rightarrow$  and all alphanumeric characters can be viewed @KS

**RPN-1250** Page 7 **RPN-1250** Page 8

### 5. Programming

Writing a sequence of keys into the program memory is called a program. The program turns the calculator into a powerful tool

The program memory consists of 4 independent program areas :

- This memory is volatile and is erased when the calculator is turned off.. Working memory which is memory for input and program execution.
- 3 backup memories in which working memory can be saved

These 3 memories are constant and preserved when the calculator is turned off

Each program area contains 98 program steps, so a total of 294 program steps are available in reserve

20 labels, numbered 0 to 9 and .0 to .9, can be used

Programming mode is activated with the key ROW

of step number followed by the text of the instruction. The content of the program is displayed alphanumerically on the display line in the form

==	70	֟ <b>֮</b>		<b>6</b>	<b>C</b>	n	Espace
rc .	م	-	<b>70</b>	<b>a</b>		u	130
רן	7	<b>L.</b>	<b>6</b>	11	<b>~</b>	10	I.
רח	S,	^ <del>-</del>	<b>"</b>	! <b>-</b>	w	<b>~</b> +	α #
s	r	<b>-</b>	0.	, ^	4 ي	•	111
۔	<u> </u>	ונ	U L	11	<b>7</b>	1	_ %
ב	<u> </u>	ב י	<b>™</b>	<b>1</b>	٥	E .	۵
1	C 1 3	0	בח כ	ט ֿ		٦ Ì	11-22

Keys and functions useful for programming:

 $[\mathfrak{SSI}]$  (Single Step) Increments the program pointer by 1 ("next step").

The **SST** key can also be used in "execution" mode

instruction is executed and the program pointer is positioned on In this mode, after pressing SST, the code of the current the next step. (step-by-step testing of a program)

183 (Back Step)

Decrements the program pointer by 1 ("previous step").

Ŷ (Delete)

displays the next part of the program Deletes the instruction at the current position of the program and

no (Insert)

key

therefore does not require a specific insertion key current instruction with offset of the following instructions and The insertion of an instruction is done automatically after the

Mond (Program)

In programming mode, PRGM exits program edit mode and In "execution" mode **PRGM** switches to programming mode.

returns the calculator to "execution" mode.

(Go To)

to the specified label 0 to 9 or .0 to .9. The **GTO** instruction is normally used to move the program pointer

the pointer, because the corresponding code would be stored in In "programming" mode, the instruction cannot be used to move the program.

return to programming mode by pressing REM perform a le jump to the specified label 0 to 9 or .0 to .9 and You must therefore exit programming mode by pressing Rem ,

RTN

(Return)

Return order after the execution of a subroutine called by GSB RTN is placed at the end of the subprogram.

But RTN can be used in "execution" mode to return the program pointer to address 0.

Starts the program or stops the program (used in "execution" mode).

r S

(Run/Stop)

Means "end of program" in programming mode

**RPN-1250** Page 9 **RPN-1250** Page 10

## 6. Keys and instructions

Each instruction has a step address followed by a title corresponding to a sequence of presses on one or more keys to express it.

# 00...09 0 8 J...9 - Numbers

Base digits in the range 0 to 9 are used to enter numbers.

They are also used to enter the mantissa of a number, enter the exponent, a memory register number, or a tag number.

The numbers are stored in the program with a code from 0 to 9 without leading zero.

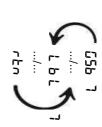

# 1.1 F GSB USb - Subroutine call

The **GSB** (GoSuB) key is used to call a subroutine using as parameter the numerical code from 0 to 9 or .0 to .9 of the called label.

If the **GSB** instruction is used in "execution" mode, the subroutine is executed immediately.

A subroutine ends with the **RTN** instruction to ensure the subroutine returns to the calling program.

#### Example :

# G RTN רבח - Return from subroutine

A subroutine called via  ${f GSB}$  ends with the  ${f RTN}$  instruction which ensures the subroutine returns just after the calling  ${f GSB}$  instruction.

In "execution" mode, **RTN** positions the program pointer on step 0.

#### 970

## ប្រភព - Go to a label

**GTO** allows you to perform an unconditional jump in a program. It has as parameter a numerical code from 0 to 9 or .0 to .9 corresponding to a label (**LbI**) of the program. When the **GTO** instruction is used in "execution" mode, the program pointer is positioned on the corresponding label.

#### Example:

## 2 F LBL LbL - Label

The **Lbl** instruction can be used to mark the start of a sequence in the program as a label.

20 labels can be used from **LbI** 0 to **LbI** 9 and from **LbI** .0 to **LbI** .9. The label number is specified as numeric parameter 0 to 9 or .0 to .9 of the **LbI** 

The label number is specified as numeric parameter 0 to 9 or .0 to .9 of the **Lbl** instruction.

You can jump to the labeled location in the program using the **GTO** jump instruction or the **GSB** subroutine call instruction..

# G TST //\_O ... //L=Y - Tests

The test instructions allow you to compare the  $\mathbf{X}$  register (display contents) with either the value zero (0) or with the  $\mathbf{Y}$  register.

If the test is satisfied, the instruction following the test instruction is executed otherwise, the command following the test is ignored and execution continues after.

## The comparative tests are :

comparison between X and zero

<b>G</b> 1ST 2	<b>G</b> TST √{	G TST S	G TST 4	G TST ®	G TST 7
X<=0	X<0	X>=0	X>0	X<>0	X=0
11-20	וירם	117-0	מרוו	וור שם	11:0

## comparison between X and $m{Y}$

G	G	G	G	G	G
TST	TST	TST	TST	TST	TST
0	0	0	0	0	0
2	B	ලි	4	☺	8
X<=Y	X <y< th=""><th>X&gt;=Y</th><th>Х&gt;Ү</th><th>Х&lt;&gt;Y</th><th>Х=Ү</th></y<>	X>=Y	Х>Ү	Х<>Y	Х=Ү

**RPN-1250** Page 11 **RPN-1250** Page 12

## bSt - Back step

The BST (Back Step) key in programming mode returns to the previous step.

# F Sυ 5υ - Save in constant memory

In "execution" mode the **SV** (Save) function allows saving in constant memory (or continuous memory) of registers and the stack.

In programming mode, programs can be saved in 3 constant memory zones of your choice by specifying 1, 2 or 3 behind the  $\bf SV$  command.

# G LD Ld - Load from constant memory

In "execution" mode, the **LD** (Load) function allows you to reload the registers and the stack saved in constant memory (or continuous memory).

In programming mode, a program can be reloaded from one of the 3 constant memory zones of your choice by specifying 1, 2 or 3 behind the **LD** command..

## SST 55Ł - Step forward

The **SST** (Single Step) key advances one step in programming mode. In "execution" mode, the program instruction, on which the pointer is positioned, is executed, allowing the program to be executed step by step for debugging purposes. Warning: in this case of step-by-step testing of the program if a subroutine is called, the return of the subprogram (**RTN**) works as in "execution" mode and returns to step 0.

## 1.4 F PSE PRUSE - Pause

The **Pause** command stops program execution briefly and displays the contents of the **X** register for the duration of the pause.

## G VIEW س E - View register

In a program, the **VIEW** command displays the contents of a register without stopping program execution.

### 

The **R/S** (Run/Stop) key can be used to start or stop a running program.

At startup, the program starts executing from the current program step (the current address can be found by switching to **PRGM** programming mode).

In programming mode **R/S** indicates stopping of the program.

**RPN-1250** 

## F Shift key F

The **F** key is used to change the meaning of the next key to an alternate function. After pressing **F**, the alternative function (in orange) of the next key is then executed A second press on **F** activates the alternative function **G**. A third press of **F** cancels the previous presses of **F**.

The title of the  $\mathbf{F}$  key is not recorded in the program; it is the alternative title of the following key which is then displayed.

#### Example:

ln is actually obtained by pressing F 🚇 and displays 🖒 n

## G Shift key G

The  ${\bf G}$  key is used to change the meaning of the next key to an alternate function. This  ${\bf G}$  function is already an alternative function of the  ${\bf F}$  key.

After two successive presses of  $\mathbf{G}$ , the alternative function (in blue) of the next key is then executed.

A third press on **G** cancels the previous presses on **G**.

The name of the  ${\bf G}$  key is not recorded in the program, it is the alternative name of the next key which is then displayed.

#### Example:

ex is obtained by G & but in reality by pressing on F F &

# 2.2 F P nteger part

The **IP** (INTeger Part) key is used to remove digits after the decimal point from the number and to reduce the number to an integer.

The function has the same meaning as rounding to zero.

#### Example :

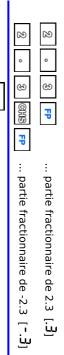

Page 13 **RPN-1250** Page 14

The **FP** (FRACtional Part) key is used to remove the digits before the decimal point from the number and to reduce the number to a fractional number.

#### Example :

**PRGM** enables or disables programming mode.

MORA

Prน็ก - Programming

# 2.3 F EEX EE!! - Entering an exponent of ten

The **EEX** function allows you to enter a number multiplied by a power of 10.

If the key is pressed while entering a number, that entry displays the exponent at 00 while awaiting entry.

If the  ${\bf X}$  register (display) is at zero, pressing **EEX** gives 1 as the  ${\bf X}$  register value and displays the exponent at 00 while waiting for its entry.

The exponent can be negative using the **CHS** function.

In the event of overflow, the calculator displays outrflow

The **Nop** (No Operation) command is an "empty" command that does not perform any operations. It is only used to fill an unused step in the program.

# ©೫೩ ch5 - Change of sign

The **CHS** key changes the sign of the number on the display.

Its use while entering the exponent of a number (power of ten) changes the sign of this exponent.

# F Fix F, H - Number of decimal places

Using the **Fix** key, the number displayed on the screen is rounded to the specified number of decimal places.

The number 0 to 6 is entered as a parameter, representing the number of decimal places after the decimal point : 0 to 6.

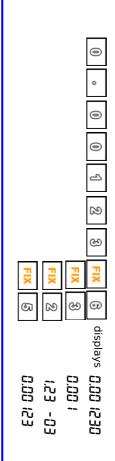

In rounding mode, the number is padded from the right with zeros, up to the specified number of decimal places.

Rounding only affects the number display. Internally, the number ( $\mathbf{X}$  register) continues to be memorized in full.

The rounding mode set also affects how very small numbers are displayed

If the number of decimal places to display only concerns zero decimal places, the number is displayed in negative powers of 10.

#### Examples :

# G SCI Sc. - Scientific notation

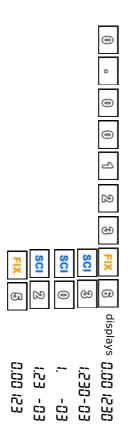

Using the **SCI** key, the number displayed on the screen is displayed as a power of ten rounded to the specified number of decimal places. The number 0 to 3 is entered as a parameter, representing the number of decimal places after the decimal point 0 to 3.

In rounding mode, the number is padded from the right with zeros, up to the specified number of decimal places.

Rounding only affects the number display. Internally, the number (X register) continues

#### Examples :

to be memorized in full

**RPN-1250** Page 15 **RPN-1250** Page 16

register X) according to the principle of Reverse Polish Notation (RPN). The sign  $\div$  allows you to divide the first operand (in the stack) by the second operand (in

#### Example:

Division of 2.2 by 0.5

5 ກ - Sinus

The angle must be entered in radian. The **sin** function calculates the sine of an angle in radians

If the angle is in degrees it must first be converted into radians using the function

Deg-Rad.

#### Example :

sin(9°) 1 →Rad SIN gives 0. 156434

G ASIN ASIN - Arcsinus

The angle must be entered in radians. The **sin-1** (Arcsine) function calculates the arcsine of an angle in radians.

If the angle is in degrees it must first be converted into radians using the function Deg-Rad

## כםל - Cosine

The **cos** function calculates the cosine of an angle in radians

The angle must be entered in radian.

If the angle is in degrees it must first be converted into radians using the function Deg-Rad

G ACOS Rco5 - Arccosine

The angle must be entered in radians. The **cos-1** (Arccosine) function calculates the arccosine of an angle in radians

If the angle is in degrees it must first be converted into radians using the function Deg-Rad

3. 3 ヒብ - Tangent

The **tan** function calculates the tangent of an angle in radians

The angle must be entered in radian.

If the angle is in degrees it must first be converted into radians using the function

Deg-Rad

The angle must be entered in radians. The **tan-1** (Arctangent) function calculates the arctangent of an angle in radians.

Deg-Rad If the angle is in degrees it must first be converted into radians using the function

**RPN-1250** 

# 5ko - Store in a registry

STO (Store) allows to store the displayed number in the data register 0 to 9 or .0 to .9. Register number 0 to 9 or .0 to .9 is entered as an instruction parameter

register number (0 to 9 or .0 to .9) entered as a parameter STO (Store) can also be used "arithmetically" by inserting an operator before the

× ÷ 8 В ot multiplies the contents of register .1 by 4 adds 2 to the contents of register 7

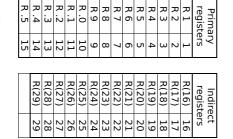

STO (Store) allows you to modify the contents of the stack registers ( X, Y, Z ou T). Arithmetic operators can also be used Warning: entering a number before the STO shifts the stack!

affects the Y register in the stack. affects the **T** register in the stack affects the **Z** register in the stack. affects the  $\mathbf{X}$  register in the stack

indirectly in registers 1 to 29, register 0 being used as an In addition to direct storage functions in registers 0 to 9, .0 to .9 and stack, STO (Store) can also store data

registers for the first 15 which therefore correspond to 14 which can only be used in indirect addressing registers R0 to R.5, and indirect registers for the following These 29 registers are the "standard" or "primary"

The key to signify "Index" is the key initial

#### Example

then stores the value 24 in the indirect register (R7) stores 7 as index value in register 0,

multiplies by ten the contents of the register whose index is stored in register 0.

Page 17 **RPN-1250** Page 18

# rck - Recall from a registry

**RCL** (Recall) is used to recall a number from data register 0 to 9 or .0 to .9 to the

Register number 0 to 9 or .0 to .9 is entered as an instruction parameter

register number (0 to 9 or .0 to .9) entered as a parameter RCL (Recall) can also be used "arithmetically" by inserting an operator before the

#### Example:

RCL RCL ÷ 8  $\rfloor$  recalls the contents of register .1 and multiplies by 4 recalls the contents of register 7 and adds 2

displayed value. Note : this arithmetic operation does not affect the contents of the register but only the

RCL (Recall) allows you to recall the contents of a register from the stack X, Y, Z or T. Note : the number displayed shifts the stack!

Arithmetic operators can also be used

recalls the register  $oldsymbol{Y}$  from the stack recalls the register **X** from the stack

recalls the register **Z** from the stack

recalls the register **T** from the stack

to 9, .0 to .9 and from the stack, **RCL** (Recall) can also being used as index. In addition to the direct recall functions from registers 0 recall data indirectly from registers 1 to 29, register 0

registers for the first 15 which therefore correspond to registers R0 to R.5, and indirect registers for the following These 29 registers are the "standard" or "primary" 14 which can only be used in indirect addressing

The key to signify "Index" is the key amax

							ď	2								
R .5	R .4	R .3	R .2	R .1	R .0	R 9	R 8	R 7	R 6	R 5	R 4	R 3	R 2	R 1	Primary registers	,
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	ers	
																_
	R(29)	R(28)	R(27)	R(26)	R(25)	R(24)	R(23)	R(22)	R(21)	R(20)	R(19)	R(18)	R(17)	R(16)	Indirect registers	-
	29	28	27	26	25	24	23	22	21	20	19	18	17	16	ers	•

#### Example

stores 7 as index value in register 0,

then recalls the value contained in the indirect register (R7)

 $\Sigma$ recalls the contents of the register whose index is stored in register 0 and multiplies the display by 10.

RCL

 $\bowtie$ 

The sign **X** allows you to multiply the first operand (in the stack) by the second operand - - Multiplication

(in register X) according to the principle of Reverse Polish Notation (RPN).

#### Example:

Multiplication of 2.2 by 0.5

# Ln - Natural logarithm

**In** calculates the natural logarithm of the displayed number

to be calculated. This natural logarithm uses Euler's constant as a base with the value 2.718281828459

The argument of the In function must be a non-zero positive number

error), as error indication. In case of zero or negative number, the display will show the value dt Error (data

#### Example:

ග calculates the natural logarithm of 5 = 1.509438

# EliP - Natural exponent

2.718281828459) raised to the power X The natural exponent is calculated from Euler's constant (value

#### Example:

calculates the natural exponent of  $5 = \{48.4 \}$ 

# Lစပ် - Decimal logarithm

**LOG** calculates the decimal logarithm of the displayed number

The argument of the LOG function must be a non-zero positive number

error), as error indication. In case of zero or negative number, the display will show the value dt Error (data

#### Example:

calculates the natural logarithm of 5 = 0.698970

**RPN-1250** Page 19 **RPN-1250** Page 20

 ${f 10}^{
m x}$  calculates the decimal exponent of the number  ${f X}$  displayed, i.e. 10 raised to the power of X

#### Example:

ම 10x

calculates the decimal exponent of 5 = 100000

### 4.3 59ר ל - Square root

 ${f VX}$  (SQRT) allows you to calculate the square root of a number. The number must not be negative

error), as error indication In the case of a negative number, the display will show the value dt Error (data

### G X<sup>2</sup> 59r - Square of a number

The  $\mathbf{X}^2$  function calculates the square of a number, or the multiple of a number by itself

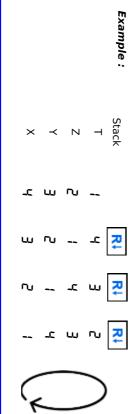

# SuRP - Exchange of X and Y registers

With the x<>y key, it is possible to swap the X and Y registers The  ${f X}$  register is the working register and also the display contents.

The  $\mathbf{Y}$  register is the register preceding the X register in the stack RPN

# าฮอนิก - Scrolling the stack down

permuting them in cascade. With the **R down** key, it is possible to scroll through the registers of the stack by

## - - Substraction

0

operand (in the stack) according to the principle of Reverse Polish Notation (RPN). The sign - allows you to subtract the second operand (in register X) from the first

#### Example :

Subtraction of 0.5 from 2.2

**RPN-1250** Page 21

## 5.1 ੀਈ - Multiplicative inverse

The 1/x function allows you to calculate the inverse of a number.

If the number is zero, the display will show the value dt Error (data error), as error indication.

## " - Exponentiation

the second operand X (displayed in the X register) The **y^x** instruction raises the first operand **Y** (in the stack) to the power expressed by

#### Example:

ලා

yx elevation of 3 to the power of 7 =n

60

# ่ ก-้ก้ก - Convert Inches to millimeters

The **IN-MM** function converts inches to millimeters

1 " = 25.4 mm

representing 1/12 of a foot The inch is a unit of length used in the Anglo-Saxon system of measurement units

### G ↑ mm กัก - n - Convert Millimeters to Inches

The **MM-IN** function converts millimeters to inches. 1 mm = 0.039370 "

thousandth of a meter. The millimeter is a unit of length used in the metric system, equivalent to one

# ก้ - + ก้ - Convert Miles to kilometers

The MI-KM function allows you to convert miles to kilometers.

1 mi = 1.60934 km

equivalent to 5,280 feet or 1,760 yards The mile is a unit of length used in the Anglo-Saxon system of measurement units

### G tkm +กั-กั - Convert Kilometers to miles

The KM-MI function converts kilometers to miles.

The kilometer is a unit of length used in the metric system, equivalent to 1000 meters.

# Lb-Ին - Convert Pounds to kilograms

The **LB-KG** function converts pounds to kilograms.

1 lb = 0.45359 kg

equivalent to 16 Ounces (OZ) The pound is a unit of weight used in the Anglo-Saxon system of measurement units

**RPN-1250** Page 22

The KG-LB function converts kilograms to pounds

1 kg = 2.20462 lb

The kilogram is a unit of weight used in the metric system, equivalent to 1000 grams.

the stack) according to the principle of Reverse Polish Notation (RPN). The sign + allows you to add the second operand (in register X) to the first operand (in

#### Example :

Addition of 2.2 and 0.5

# בלר - Clearing the display

**CLR** clears the **X** register so the display.

**ALL** erase all data :

- the RPN stack (X, Y, Z, T),
- all registers (0 to 9 and .0 to .9)

- In "execution" mode the "Back" function erases the last digit entered
- In programming mode the "Back" function erases the current step

The  $\pi$  (Pi) key is used to enter the Archimedes constant, the value of 3,141592.

Radian. The **Deg-Rad** function converts an angle value in degrees into an angle value in

 $1^{\circ} \times \pi / 180 = 0.017453 \text{ rad}$ 

# F-c - Convert Farenheit to Celsius

The  ${}^{\circ}F^{\circ}C$  function converts degrees Farenheit to degrees Celsius. 1  ${}^{\circ}F = -17.222 {}^{\circ}C$ 

is set at 32 degrees, while the boiling point of water is set at 212 degrees (scale divided On the Fahrenheit scale, primarily used in the United States, the freezing point of water into 180 intervals).

### G †°C ς-F - Convert Celsius to Farenheit

The °C-°F function converts degrees Celsius to degrees Farenheit.  $1 \, ^{\circ}\text{C} = 33.800 \, ^{\circ}\text{F}$ 

measurement for temperature, the freezing point of water is set at 0 degrees, and the On the Celsius (centigrade) scale, used in most countries as the standard unit of boiling point of water is set at 100 degrees (scale divided into 100 intervals).

## . - Decimal point

0

It is also used to prefix registers .0 to .9 and labels .0 to .9 The period (,) is the separator of whole digits and decimal digits of a number

# LRSEII - Last X

The LastX function allows you to recall the last known operand in register X.

## Enter a number

shifting the stack (Z into T, Y into Z, X into Y) while keeping this number in the register X (display) until the introduction of a new number. The **Enter** key validates the entry of a number and copies it into the Y register by

**RPN-1250** Page 23 **RPN-1250** Page 24

## 7. Example programs

1. Forensics
Classic calculator test to test calculation accuracy.

of the accuracy of scientific calculators applies the following calculation : This "forensics" algorithm invented by Mike Sebastian to quickly provide a comparison

arcsin(arccos(arctan(tan(cos(sin(9))))))

9 sin cos tan atan acos asin

Use :

.. start the calculation

#### Program :

```
o \omega \omega \omega \omega \omega \omega \omega \omega
                                                                                                                      <mark>dE፲-</mark>\Gamma R converts the angle expressed in degrees into radians
       LbL ជ | program start label
                                                                                                                                         F, H \mathbf{g} sets the decimal places to the maximum (6 in reality)
                                                                                                     cosine
                                                                                                                sinus
                                                                 arcsine
                                     > convert the angle obtained into degrees for comparison
                                                                          arccosine
                                                                                    arctangent
                                                                                            tangent
```

2. Factorial

Calculating the factorial of a number

Use :

number for which the factorial must be calculated

... launches the factorial calculation

#### Program:

decrements the rank of the calculation stores the number n in register 1 which multiplies the result end of program reminder result then return to the start of the loop reminder of the rank value rank of calculation label for iterative loop in register 2 stores the value 1 set decimal places to 0 program start label if different from zero

n :-

Result: 8.99996

**RPN-1250** Page 25 **RPN-1250** Page 26

end of program

#### 3. Fibonacci

Calculates a Fibonacci number of rank n

#### Use :

rank for which we must find the Fibonacci number

... start the search

#### Program:

```
5 brogram start label stores the number n in register .0
                                                                                                                                              program start label
     reminder of the result
set decimal places to 0
                                                                                         decrements the rank of the calculation
```

Calculates the perimeter and area of ??a circle from the radius

#### Use:

radius of the circle

calculates and displays the perimeter

calculates and displays the area

```
recall radius r from register .0

| LbL 5 | set decimal places to 2 |
| Stores the radius r in register .0 |
| Colculates the perimeter r × 2 × π |
| Colculates the perimeter r × 2 × π |
| Colculates the area r² × π |
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |> calculates the perimeter r x 2 x \pi
```

Page 27 **RPN-1250** Page 28

Page 30

approach the factorial of a number. Garden near Stirling and died on December 5, 1770 in Edinburgh) makes it possible to The Stirling formula (James Stirling, Scottish mathematician, born in May 1692

5. Stirling

$$n! \sim \sqrt{2\pi n} \left(\frac{n}{e}\right)^n$$

This improved formula will provide a better approach:

$$n! \sim \sqrt{2\pi n} \left(rac{n}{\mathrm{e}}
ight)^n \left(1 + rac{1}{12\,n}
ight)$$

of a number is usually done on programmable calculators using an iterative loop. When the function **n!** (factorial) does not exist on a calculator, this factorial calculation

excessive in time for large numbers. This kind of calculation can be very inexpensive in terms of number of steps but

On the other hand, the Stirling formula gives an approximation of the result very quickly but costs a few program steps. (see factorial program page 24)

#### Use:

number for which the factorial must be calculated

... launches the factorial calculation

#### Program:

Binet's formula (Jacques Philippe Marie Binet, French mathematician and astronomer, term of the Fibonacci sequence. born in Rennes on February 2, 1786 and died in Paris on May 12, 1856) provides the nth

$$\mathbf{n} = \frac{1}{\sqrt{5}} \left( \frac{1 + \sqrt{5}}{2} \right)^{n} - \frac{1}{\sqrt{5}} \left( \frac{1 - \sqrt{5}}{2} \right)^{n}$$

calculators using a loop up to n. (see Fibonacci program page 25) The calculation of the nth term of the Fibonacci sequence is usually done on programmable

This kind of calculation can be very inexpensive in terms of number of steps but excessive in time tor high values ??ot n.

On the other hand, Binet's formula gives the result very quickly but costs many program steps.

#### Use :

rang pour lequel il faut rechercher le nombre de Fibonacci

... launches the calculation

#### Program:

F, :: 0

**7. GCD**One of the classic little programs for programming calculators...

the language of the newly acquired calculator.. Many programmers started with these small programs whose usefulness was to learn

#### Use :

<u>n</u>1 first number

n2 second number

calculates and displays the GCD

#### Program:

õ	==	63	9	00	-1	5	5	T	Ę	5	
רכל 2	구	٦	E 035	לכנ 5	רכל !	197	1 035	rdoŭn	rdoŭn	5 035	197
75	62	55	2	않	ã	ã	=======================================	õì	ŝ	ĩ	ũ

#### 8. Birthday

same birthday (not necessarily born in the same year) in a group of n people. The birthday paradox calculates the percentage chance of finding 2 people with the

$$p(n) = 1 - \frac{365}{365} \cdot \frac{364}{365} \cdot \frac{363}{365} \cdot \dots \cdot \frac{365 - n + 1}{365}$$

make the programs more complicated. Considering leap years would change the results of the calculations little, but would To simplify, the formula chosen assumes that all years are non-leap years.

#### Use:

number of persons

... starts the percentage calculation

#### 9. Ramanujan

Ramanujan's formula allows you to calculate the factorial of a number n.

$$n! \sim \sqrt{\pi} \left(\frac{n}{e}\right)^n \sqrt[6]{8n^3 + 4n^2 + n + \frac{1}{30}}$$

died April 26, 1920 in Kumbakonam) (Srinivasa Ramanujan, Indian mathematician, born December 22, 1887 in Erode and

#### Use :

 $\supset$ number for which the factorial must be calculated

#### WELCOME TO THE RPN-1250 CALCULATOR

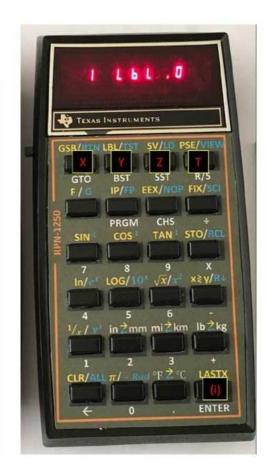

#### Page 46

#### STACK REGISTERS INDIRECT ADDRESSING

Store and Recall functions (including store and recall arithmetic) and VIEW can operate on stack registers, which are linked to the top row keys

As in the HP-29C the indirect addressing register is RO

Indirect addressing (i) works with Store, Recall (including store and recall arithmetic) and VIEW functions only (No fix (i), or GSB (i)) and is called with the [ENTER] key

#### REAL TIME CLOCK (RTC) RPN-1250+ Only

Time, Date and Day Of Week are addressed as memory registers using the [PREFIX] [PRGM] and [CHS] Keys

Time format is hh.mmss (24 hour)

Date format is mm.ddyy

Day of Week is 1~7 for Mon-Sun

RTC functions are programmable
